## Problem Set #3

You should try to solve these problems by yourself. I recommend that you start early and get help in office hours if needed. If you find it helpful to discuss problems with other students, go for it. **You do not need to turn these problems in. The goal is to be ready for the in class quiz that will cover the same or similar problems.**

### Problem 1: Asymptotic Time Complexity

Consider each of the following pairs of functions. For each pair, either  $f(n) = O(g(n))$ ,  $f(n) = \Omega(g(n))$  or  $f(n) = \Theta(g(n))$ . Determine which of these three options best captures the relationship and (briefly) explain or demonstrate why.

(a)  $f(n) = \log n^2$ ;  $g(n) = \log n + 5$

(b)  $f(n) = \sqrt{n}$ ;  $g(n) = \log n^2$

(c)  $f(n) = \log^2 n$ ;  $g(n) = \log n$

(d)  $f(n) = n$ ;  $g(n) = \log^2 n$

(e)  $f(n) = n \log n + n$ ;  $g(n) = \log n$

(f)  $f(n) = 10$ ;  $g(n) = \log 10$

(g)  $f(n) = 2^n$ ;  $g(n) = 10n^2$

(h)  $f(n) = 2^n$ ;  $g(n) = 3^n$

**Problem 2: Stable Shipping Repair**

Peripatetic Shipping Lines, Inc. is a shipping company that owns  $n$  ships and provides services to  $n$  ports. Each of its ships has a *schedule* that says, on each day of the month, which of the ports it is currently visiting, or whether it is out to sea. (You can assume the “month” here has  $m$  days for some  $m > n$ .) Each ship visits each port for exactly one day during the month. For safety reasons, PSL Inc. has the following strict requirement:

(†) *No two ships can be in the same port on the same day.*

The company wants to perform maintenance on all the ships this month, via the following scheme. They want to *truncate* each ship’s schedule; for each ship  $S_i$ , there will be some day when it arrives in its scheduled port and simply remains there for the rest of the month (for maintenance). This means that  $S_i$  will not visit the remaining ports on its schedule (if any) that month, but this is okay. So the *truncation* of  $S_i$ ’s schedule will simply consist of its original schedule up to a certain specified date on which it is in a port  $P$ ; the remainder of the truncated schedule simply has it remain in port  $P$ .

Now the company’s question to you is the following: given the schedule for each ship, find a truncation of each so that condition (†) continues to hold: no two ships are ever in the same port on the same day.

Show that such a set of truncations can always be found, and given an algorithm to find them.

**Example.** Suppose we have two ships and two ports, and the “month” has four days. Suppose that the first ship’s schedule is:

*port  $P_1$ ; at sea; port  $P_2$ ; at sea*

and the second ship’s schedule is:

*at sea; port  $P_1$ ; at sea; port  $P_2$*

Then the (only) way to choose truncations would be to have the first ship remain in port  $P_2$  starting on day 3 and have the second ship remain in port  $P_1$ , starting on day 2.

**Problem 3: Asymptotic Analysis**

Prove that  $o(g(n)) \cap \omega(g(n))$  is the empty set.

**Problem 4: Algorithm Analysis**

Consider the following basic problem. You're given an array  $A$  consisting of  $n$  integers  $A[1], A[2], \dots, A[n]$ . You'd like to output a two-dimensional  $n$ -by- $n$  array  $B$  in which  $B[i, j]$  (for  $i < j$ ) contains the sum of array entries  $A[i]$  through  $A[j]$ —that is, the sum  $A[i] + A[i+1] + \dots + A[j]$ . (The value of array entry  $B[i, j]$  is left unspecified whenever  $i \geq j$ , so it doesn't matter what is output for these values.) Below is a simple algorithm to solve this problem:

```
1  for  $i \leftarrow 1$  to  $n$ 
2      do for  $j \leftarrow i + 1$  to  $n$ 
3          Add entries  $A[i]$  through  $A[j]$ 
4          Store the result in  $B[i, j]$ 
```

- (a) Give a function  $f(n)$  that is an asymptotically tight bound on the running time of the algorithm above. Using the pseudocode above, argue that the algorithm is, in fact  $\Theta(f(n))$ .
- (b) Although the algorithm you analyzed above is the most natural way to solve the problem, it contains some highly unnecessary sources of inefficiency. Give a different algorithm to solve this problem with an asymptotically better running time than the provided algorithm.
- (c) What is the running time of your new algorithm?

**Problem 5: Algorithms and Decision Trees**

You are given 9 identical looking balls and told that one of them is slightly heavier than the others. Your task is to identify the defective ball. All you have is a balanced scale that can tell you which of the two sides is heavier or if the two sides weigh the same.

- (a) Show how to identify the heavier ball in just 2 weighings.
- (b) Give a decision tree lower bound showing that it is not possible to determine the defective ball in fewer than 2 weighings.
